TITLE: A phase triggering device for an information receiver. Class 21, No. 172353

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 13, 1965, 27

TOPIC TAGS: trigger circuit, data transmission, logic element

ABSTRACT: This Author's Certificate introduces: 1. A phase triggering device for an information receiver. The unit is designed for a more reliable triggering signal which is free from interference. Receivers are triggered for short periods of communication by transmitting recurrent combinations which are repeated n times. The transmitter is made in the form of a shift register which is closed into a ring with three outputs to a logical "OR" gate which is connected to the transmission channel. At the input of the phase triggering receiver is a decoder with three outputs to recording units. An "OR" gate is connected to the outputs of the recording units through delay lines with various delay times. These delay lines convert the three sequentially received combinations into three parallel code combinations for

Card 1/3

phase triggering device receiver. 2. A modification of this device in which the amount of equipment is reduced by using the same recording units for suppressing false signals which appear at the decoder outputs, resetting the oscillation counter in the case of false operation, and delaying the triggering signal by the length of the subsequent combinations.

PETROVSKIY, B. V.

"Transfusion of Blood During Thoracic Surgery," by Prof B. V. Petrovskiy, Corresponding Member, Academy of Medical Sciences USSR, Chair of Faculty Surgery (head, Prof B. V. Petrovskiy), Pediatrics Faculty, Second Moscow Medical Institute imeni I. V. Stalin, Problemy Gematologii i Perelivaniya Krovi, Vol 1, No 5, Sep/Oct 56, pp 36-43

The author discusses methods of intravenous drip transfusion of blood and plasma in combination with various isotonic solutions and fluids; intra-arterial transfusion, and the introduction of blood into the aorta.

A total of 161 intra-arterial transfusions were performed and 91 of them were done during operations on the esophagus, gastrectomy, pneumonectomy, pericardectomy, and the rerouting of blood from the pulmonary artery to the thoracic aorta. Special importance is attributed to the latter in cases of atrioventricular stenosis and similar operations during which the heart remains inactive for 20-30 minutes.

1086. PRESENT-DAY QUESTIONS ON HEART SURGERY IN CHILDHOOD (Russian text) - Petrovsky B. V. Surg. Clin., Fac. of Second M. Inst., Moscow - SOVETSK. MED. 1956, 8 (9-17)

Report on 110 children with congenital and acquired heart disease. Twenty patients with an open ductus arteriosus were operated upon with good results. Access was effected by an incision in the 4th left intercostal space without resection of cartilages or ribs. The duct was ligatured in 2 places. Fifteen patients with cyanosis of the tetralogy of Fallot type were operated upon, in 9 cases by-pass anastomosis was performed (with fatal results in 4). Surgical interference in the heart itself has been practised since 1953. At the beginning valvotomy of the stenosed pulmonary valve was performed through left-side thoracotomy (2 operations with good results). At present these interventions are combined with valvectomy and dilatation of the orifice of the pulmonary artery (4 operations with good results). Adhesive pericarditis was treated in 25 patients with good results after pericardiectomy in 5. Mitral commissurotomy was performed in 5 children, 13-15 yr. old, with mitral stenosis of rheumatic origin. All these children had a marked mitral stenosis and in 2 another narrowing was found beneath the valve owing to the knitting together of the chordae and the papillary muscles. In all cases the results of the operations were good.

EXCERPTA MEDICA Sec 16 Vol 7/6 Cancer June 59

21.1 Long-term observations after operation for cancer of the oesophagus and cardia (Russian text)

Pravda, 30 (B. V. Moscov, *Izv. V. P. Pirogov Inst. Surg. Acad. Med. Sci. USSR*, 1957, 1, 47, 1-4, 4 pp., Tables 7)

Of 810 patients who, during the past 10 yr., were treated for cancer of the oesophagus, 249 (30.7%) were operated on. Radical operation was performed in 79 cases (31.7%) and palliative operations including gastrostomy in 170 cases (20.0%). In cases where the tumours were located in the lower third of the oesophagus, and also in cases of advanced tumours in the middle third, left-sided transthoracic resection of the oesophagus was performed with establishment of an oesophagogastrostomy (76 operations with 18 fatalities). In all the remaining radically operated cases the patients were operated via a right-sided approach after Forek (23 operations with 8 fatalities). In only 8 of the cases was a subsequent antethoracic oesophagoplasty possible. In lesions of the cervical portion of the oesophagus resection with subsequent skin plasty was carried out. Altogether, of the 53 patients with carcinoma of the oesophagus who successfully underwent resection, 22 are alive one to 3 yr. after the operation, 7 are alive from 3 to 5 yr. and 2 are alive more than 5 yr. Almost identical late effects were obtained with Forek's operation and with resection plus simultaneous performance of intrathoracic anastomosis. In cancer of the cardia (1,040 cases), radical operations were successfully performed in 276 (26.5%) and palliative in 251 (24.1%). Transthoracic resection of the cardia was the predominant type (163 operations with 21.4% fatalities). Gastrectomy was performed on 113 patients with 30% death rate; two thirds of the operations were transthoracic, which enhanced the radical nature of the procedure. In patients of advanced age and in cases of pronounced pulmonary emphysema, gastrectomy was performed via a left-sided subcostal approach with division of the superior attachments of both rectus abdominis muscles. Of the patients operated on for cancer of the cardia, 40 are alive 3 to 5 yr. after the operation and 21 are living more than 5 yr. later. Functional results were better after cardectomy than after gastrectomy.
